High-level description

Coding decisions and structure

I wanted to try and make as much as possible load in dynamically based on previous clicks or values, which is why a lot of my HTML is really only found in the js.

I found using `` quite efficiently, which made the code easier to read and edit.

I wanted to use bootstrap especially for modals and dropdowns, where I found it a lot easier to understand. I also used it on some buttons and for some divs, where it needed to be, especially if the bootstrap css file made changes to my page.

The pages are structured, so that you have start at main.html, choose to see details of one of them. The details.html loads details about that chose one. If you from here choose to click the compare housing button, you pick another housing to compare to. When you do, you get sent to comparison.html, where initially these two are compared with different data. If you enter details.html or comparison.html without an id or two in the URL, the page doesn't work.

As I didn't have that much of input choices and filter functionalities, I added quite a bit of it. The filter menu filters out either listings that don't meet the criteria or aspects of a listing you're not interested in comparing.

The sort buttons do what you would expect them to do. I decided for now to keep them separated as making it into one button would take a lot more time.

I also added a search function at the main.html where you can put some input, and if it matches some of the data to a listing, it displays that listing.

Throughout my exam, I found better ways to do things, which meant the code on comparison.js is probably cleaner than the one in main.js due to me getting used to things and wanting to do things better.

I know some of the code is a bit repetitive, but I figured it is more important for now that it works rather than it looking great.

Use of AI

Bjarte Haaland

I have used AI to some degree, but mostly to find a bug in my code, if there is a typo somewhere I just can't find etc.
